Petrol engine (British English) or gasoline engine (American English) is an internal combustion engine with spark-ignition, designed to run on petrol (gasoline) and similar volatile fuels.. In most petrol engines, the fuel and air are usually pre-mixed before compression (although some modern petrol engines now use cylinder-direct petrol injection).The pre-mixing was formerly done in a ...

In a gasoline (petrol) internal combustion engine, before the spark is generated, the air-fuel mixture must be homogeneous.This is critical for the flame to appear around the spark and propagates into the cylinder, for a quasi-complete combustion. The electric arc (plasma) generated by the spark plug reaches temperatures of 10000 °C and triggers the combustion process.

There are two kinds of internal combustion engines currently in production: the spark ignition gasoline engine and the compression ignition diesel engine. Most of these are four-stroke cycle engines, meaning four piston strokes are needed to complete a cycle. The cycle includes four distinct processes: intake, compression, combustion and power ...

In theory, diesel engines and gasoline engines are quite similar. They are both internal combustion engines designed to convert the chemical energy available in fuel into mechanical energy. This mechanical energy moves pistons up and down inside cylinders. The pistons are connected to a crankshaft, and the up-and-down motion of the pistons, known as linear motion, creates the rotary motion ...

The internal combustion engine is a heat engine.It's working principle is based on the variation of pressure and volume inside the engine's cylinders. All heat engines are characterized by a pressure-volume diagram, also known as pV diagram, which basically shows the variation of the pressure in the cylinder function of its volume, for a complete engine cycle.

Gasoline engine - Gasoline engine - Two-stroke cycle: In the original two-stroke cycle (as developed in 1878), the compression and power stroke of the four-stroke cycle are carried out without the inlet and exhaust strokes, thus requiring only one revolution of the crankshaft to complete the cycle. The fresh fuel mixture is forced into the cylinder through circumferential ports by a rotary ...
