Among these is lincRNA-Cox2, a dynamically regulated gene that broadly controls immune gene expression. To evaluate the in vivo functions of this lincRNA, we characterized multiple models of lincRNA-Cox2-deficient mice. LincRNA-Cox2-deficient macrophages and murine tissues had altered expression of inflammatory genes.

Elling et al. utilize a number of lincRNA-Cox2 genetic models to show that lincRNA-Cox2 can regulate its neighboring gene Ptgs2 (Cox2) through an enhancer RNA mechanism. They generate a lincRNA-Cox2 splicing-deficient mouse and confirm that lincRNA-Cox2 functions in trans to regulate immune genes following LPS-induced endotoxic shock.

### Genetics of autoimmune diseases: insights from population ...

For example, the identification of rare Mendelian autoimmune disorders in humans (e.g., mutations in AIRE; Mathis and Benoist, 2009) has provided enormous insight into basic mechanisms of autoimmunity, enhanced by similar phenotypic manifestations in corresponding murine genetic models. Conversely, the development of single-gene, murine models of disease has provided significant insight; the identification of correlative disease associations in a given gene through GWAS in humans would ...

### **Unraveling the Genetics of Autoimmunity**

Genetic risk factors play an important role in autoimmune disease susceptibility. Recent advances genotyping techniques, statistical methods, and the organization of large patient cohorts have facilitated explosive progress in this field, and our understanding of the genetic architecture of human autoimmunity is rapidly expanding.

Genetic and transgenic models have proven to be of great value in the study of the GHRH-GHS-GH-IGF-1 axis. The variety of models with unique disturbances in the pituitary signaling system associated with GH secretion has provided the means to determine the relative contribution of the multiple pathways that regulate GH secretion and to determine the downstream consequences of altered function of individual components.

This paper underlines the need of developing animal models to study the diverse complications of celiac disease (CD). CD is a multifactorial condition requiring both an exogenous element (gluten) and complex genetic factors; moreover, CD is associated to several endocrine, immune and reproductive diseases, whose onset may be influenced by other environmental factors as well.

Mouse models have been instrumental in the development of some types of immunotherapy, several presenters noted at the start of the meeting. A landmark 1996 study used mouse models to show that targeting certain checkpoint proteins on immune cells could release the “brakes” on the immune system, enhancing the ability of immune cells to attack tumors.

Abstract. This chapter describes four murine models of autoimmune diseases: two related to autoimmune myocarditis and two related to autoimmune thyroiditis. The first model, Coxsackie virus B3 (CB3)-induced myocarditis, results in the development of acute myocarditis in susceptible as well as resistant mouse strains, whereas chronic myocarditis develops only in genetically susceptible mice.

Background: Immune checkpoint inhibitor (ICI) therapy is often accompanied by immune-related pathology, with an increasing occurrence of high-risk ICI-related myocarditis. Understanding the mechanisms involved in this side effect could enable the development of management strategies.

In addition, allergy and autoimmune disease variants had shared immune pathways within regulatory regions in immune cells, which were distinct from other diseases. The authors hypothesized that identifying shared genetic mechanisms might increase our understanding of allergy and autoimmune disease and their complex relationship.

Although the mice have mostly the same genetic profiles, differences in cancer-promoting gene mutations, therapeutic response rates and immune composition make each model unique. Importantly, immune checkpoint inhibitors slow tumor growth in two of the models but are ineffective in the other two.
