More types of organic compound. Carboxylic acids. Carboxylic acids contain the -COOH group, which is better written out in full as: Carboxylic acids are shown by the ending oic acid. When you count the carbon chain, you have to remember to include the carbon in the -COOH group. That carbon is always thought of as number 1 in the chain.

A modern organic name is simply a code. Each part of the name gives you some useful information about the compound. For example, to understand the name 2-methylpropan-1-ol you need to take the name to pieces. The prop in the middle tells you how many carbon atoms there are in the longest chain (in this case, 3).

Note: There are all sorts of ways of naming ethers.For UK A level purposes, the problem doesn't arise - you almost certainly won't have to name them. If you have looked at the chemistry of halogenoalkanes, you may be aware that there is a competition between substitution and elimination when they react with hydroxide ions.

Naming Organic Compounds. The increasingly large number of organic compounds identified with each passing day, together with the fact that many of these compounds are isomers of other compounds, requires that a systematic nomenclature system be developed. Just as each distinct compound has a unique molecular structure which can be designated by ...

Organic chemistry is the study of all organic compounds. Organic chemistry is a very vast and complex subject. There are millions of known organic compounds, which is far more than the number of inorganic compounds. The reason lies within the uniqueness of carbon's structure and bonding capabilities.

The Chemical Abstract Service has adopted a nomenclature system in which the suffix -amine is attached to the root alkyl name. For 1^o-amines such as butanamine (first example) this is analogous to IUPAC alcohol nomenclature (-ol suffix). The additional nitrogen substituents in 2^o and 3^o-amines are designated by the prefix N-before the group name. These CA names are colored magenta in the diagram.

The IUPAC developed the systematic naming system (nomenclature) to allow many of the organic compounds to be named in a logical fashion by considering the structural features of the molecule. This systematic nomenclature arrives at the compound name in the following order: Step 1 - Longest carbon chain Step 2 - Unsaturation

Many organic compounds found in nature contain rings of carbon atoms. These compounds are known as cycloalkanes. Cycloalkanes have one or more rings of carbon atoms. Cycloalkanes only contain carbon-hydrogen bonds and carbon-carbon single bonds.

IUPAC system and IUPAC rules of naming of amines Aliphatic amines are named by adding the suffix amine to the name of the alkyl group and it is written as one word. E.g., C 2 H 5 NH 2 is Ethylamine. When two or more alkyl groups in secondary or tertiary amines are some, the prefix di or tri is used.
