The Stress Test MRI used to examine the lumbar spine visualizes the anatomy in both supine and weight-bearing positions, and shows increased pressure applied to the spine while standing. When the patient is lying down during a traditional supine MRI examination, stresses on the discs are slight or non-existent, and space for the nerves is increased within the spinal canal.

OPEN INMOTION MRI is weight-bearing, this means the patient’s position becomes an integral part of the exam’s outcome. This is especially important for diagnosing musculoskeletal conditions. Since the force of gravity generates bio-mechanical changes in anatomy, INMOTION MRI in a natural, stand-up position allows physicians to attain important additional information compared to traditional MRI.

Previous reports have been published on sectional weight-bearing extremity imaging by applying axial loads to joints during traditional CT or MRI scans in the supine position and by using dedicated MRI instruments for scanning in the upright position [6–8]. Advantages of the new CBCT-based extremity scanner over these methods are the fast image acquisition time and imaging in the natural standing position, in addition to supine scanning.
